# C2 W2 Lab 3 Feature Selection

January 1, 2025

# 1 Ungraded Lab: Feature Selection

Feature selection involves picking the set of features that are most relevant to the target variable. This helps in reducing the complexity of your model, as well as minimizing the resources required for training and inference. This has greater effect in production models where you maybe dealing with terabytes of data or serving millions of requests.

In this notebook, you will run through the different techniques in performing feature selection on the Breast Cancer Dataset. Most of the modules will come from scikit-learn, one of the most commonly used machine learning libraries. It features various machine learning algorithms and has built-in implementations of different feature selection methods. Using these, you will be able to compare which method works best for this particular dataset.

## 1.1 Imports

```
[2]: # for data processing and manipulation
     import pandas as pd
     import numpy as np
     # scikit-learn modules for feature selection and model evaluation
     from sklearn.ensemble import RandomForestClassifier
     from sklearn.feature selection import RFE, SelectKBest, SelectFromModel, chi2,
     →f classif
     from sklearn.model_selection import train_test_split
     from sklearn.metrics import accuracy_score, roc_auc_score, precision_score,
     →recall_score, f1_score
     from sklearn.svm import LinearSVC
     from sklearn.feature selection import SelectFromModel
     from sklearn.preprocessing import StandardScaler, MinMaxScaler
     # libraries for visualization
     import seaborn as sns
     import matplotlib
     import matplotlib.pyplot as plt
```

# 1.2 Load the dataset

We've already downloaded the CSV in your workspace. Run the cell below to load it in the lab environment and inspect its properties.

```
[3]: # Load the dataset
df = pd.read_csv('./data/breast_cancer_data.csv')

# Print datatypes
print(df.dtypes)

# Describe columns
df.describe(include='all')
```

[5 rows x 33 columns]

## 1.3 Remove Unwanted Features

You can remove features that are not needed when making predictions. The column Unnamed: 32 has NaN values for all rows. Moreover, the id is just an arbitrary number assigned to patients and has nothing to do with the diagnosis. Hence, you can remove them from the dataset.

```
[5]: # Check if there are null values in any of the columns. You will see `Unnamed:□

→ 32` has a lot.

df.isna().sum()
```

```

## 1.4 Integer Encode Diagnosis

You may have realized that the target column, diagnosis, is encoded as a string type categorical variable: M for malignant and B for benign. You need to convert these into integers before training the model. Since there are only two classes, you can use 0 for benign and 1 for malignant. Let's create a column diagnosis int containing this integer representation.

```
[7]: # Integer encode the target variable, diagnosis
df ["diagnosis_int"] = (df ["diagnosis"] == 'M').astype('int')

# Drop the previous string column
df.drop(['diagnosis'], axis=1, inplace=True)

# Check the new column
df.head()
```

```
[7]:
        radius mean
                      texture mean
                                     perimeter mean
                                                      area mean
                                                                   smoothness mean
                                                                           0.11840

```

[5 rows x 31 columns]

#### 1.5 Model Performance

Next, split the dataset into feature vectors X and target vector (diagnosis) Y to fit a Random-ForestClassifier. You will then compare the performance of each feature selection technique, using accuracy, roc, precision, recall and f1-score as evaluation metrics.

```
[8]: # Split feature and target vectors
X = df.drop("diagnosis_int", 1)
Y = df["diagnosis_int"]
```

#### 1.5.1 Fit the Model and Calculate Metrics

You will define helper functions to train your model and use the scikit-learn modules to evaluate your results.

```
[9]: def fit_model(X, Y):
    '''Use a RandomForestClassifier for this problem.'''

# define the model to use
model = RandomForestClassifier(criterion='entropy', random_state=47)
```

```
model.fit(X, Y)
          return model
[10]: def calculate_metrics(model, X_test_scaled, Y_test):
          '''Get model evaluation metrics on the test set.'''
          # Get model predictions
          y_predict_r = model.predict(X_test_scaled)
          # Calculate evaluation metrics for assesing performance of the model.
          acc = accuracy_score(Y_test, y_predict_r)
          roc = roc_auc_score(Y_test, y_predict_r)
          prec = precision_score(Y_test, y_predict_r)
          rec = recall_score(Y_test, y_predict_r)
          f1 = f1_score(Y_test, y_predict_r)
          return acc, roc, prec, rec, f1
[11]: def train_and_get_metrics(X, Y):
          '''Train a Random Forest Classifier and get evaluation metrics'''
          # Split train and test sets
          X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size = 0.
       →2,stratify=Y, random_state = 123)
          # All features of dataset are float values. You normalize all features of \Box
       → the train and test dataset here.
          scaler = StandardScaler().fit(X_train)
          X_train_scaled = scaler.transform(X_train)
          X_test_scaled = scaler.transform(X_test)
          # Call the fit model function to train the model on the normalized features \Box
       \rightarrow and the diagnosis values
          model = fit_model(X_train_scaled, Y_train)
          # Make predictions on test dataset and calculate metrics.
          acc, roc, prec, rec, f1 = calculate_metrics(model, X_test_scaled, Y_test)
          return acc, roc, prec, rec, f1
[12]: def evaluate_model_on_features(X, Y):
          '''Train model and display evaluation metrics.'''
          # Train the model, predict values and get metrics
```

# Train the model

```
acc, roc, prec, rec, f1 = train_and_get_metrics(X, Y)

# Construct a dataframe to display metrics.
display_df = pd.DataFrame([[acc, roc, prec, rec, f1, X.shape[1]]], ___
→columns=["Accuracy", "ROC", "Precision", "Recall", "F1 Score", 'Feature__
→Count'])

return display_df
```

Now you can train the model with all features included then calculate the metrics. This will be your baseline and you will compare this to the next outputs when you do feature selection.

```
[13]: # Calculate evaluation metrics
all_features_eval_df = evaluate_model_on_features(X, Y)
all_features_eval_df.index = ['All features']

# Initialize results dataframe
results = all_features_eval_df

# Check the metrics
results.head()
```

[13]: Accuracy ROC Precision Recall F1 Score Feature Count All features 0.964912 0.967262 0.931818 0.97619 0.953488 30

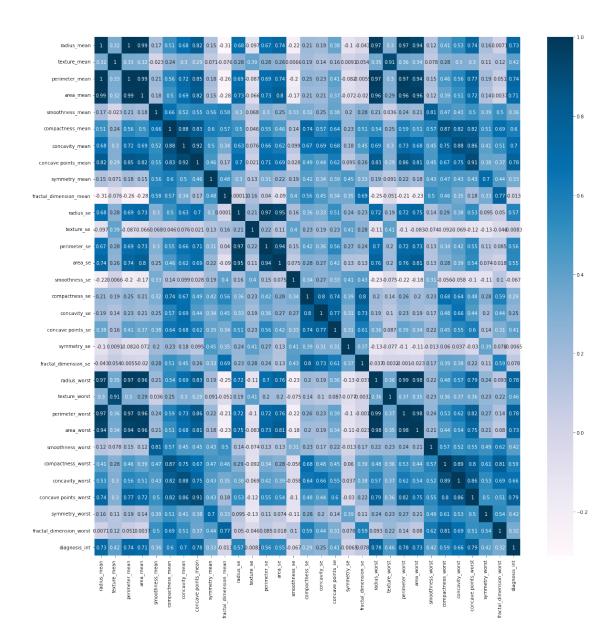

#### 1.6 Correlation Matrix

It is a good idea to calculate and visualize the correlation matrix of a data frame to see which features have high correlation. You can do that with just a few lines as shown below. The Pandas corr() method computes the Pearson correlation by default and you will plot it with Matlab PyPlot and Seaborn. The darker blue boxes show features with high positive correlation while white ones indicate high negative correlation. The diagonals will have 1's because the feature is mapped on to itself.

```
[14]: # Set figure size
plt.figure(figsize = (20,20))

# Calculate correlation matrix
cor = df.corr()

# Plot the correlation matrix
sns.heatmap(cor, annot = True, cmap = plt.cm.PuBu)
plt.show()
```

#### 1.7 Filter Methods

Let's start feature selection with filter methods. This type of feature selection uses statistical methods to rank a given set of features. Moreover, it does this ranking regardless of the model you will be training on (i.e. you only need the feature values). When using these, it is important to note the types of features and target variable you have. Here are a few examples:

- Pearson Correlation (numeric features numeric target, exception: when target is 0/1 coded)
- ANOVA f-test (numeric features categorical target)
- Chi-squared (categorical features categorical target)

Let's use some of these in the next cells.

## 1.7.1 Correlation with the target variable

Let's start by determining which features are strongly correlated with the diagnosis (i.e. the target variable). Since we have numeric features and our target, although categorical, is 0/1 coded, we can use Pearson correlation to compute the scores for each feature. This is also categorized as supervised feature selection because we're taking into account the relationship of each feature with the target variable. Moreover, since only one variable's relationship to the target is taken at a time, this falls under univariate feature selection.

```
[18]: # Get the absolute value of the correlation
    cor_target = abs(cor["diagnosis_int"])

# Select highly correlated features (thresold = 0.2)
    relevant_features = cor_target[cor_target>0.2]

# Collect the names of the features
    names = [index for index, value in relevant_features.iteritems()]

# Drop the target variable from the results
    names.remove('diagnosis_int')

# Display the results
    print(names)
```

```

Feature Count All features 30 Strong features 25

### 1.7.2 Correlation with other features

You will now eliminate features which are highly correlated with each other. This helps remove redundant features thus resulting in a simpler model. Since the scores are calculated regardless of the target variable, this can be categorized under *unsupervised* feature selection.

For this, you will plot the correlation matrix of the features selected previously. Let's first visualize the correlation matrix again.

```
[20]: # Set figure size plt.figure(figsize=(20,20))
```

```
# Calculate the correlation matrix for target relevant features that you_
→ previously determined

new_corr = df[names].corr()

# Visualize the correlation matrix

sns.heatmap(new_corr, annot=True, cmap=plt.cm.Blues)

plt.show()
```

You will see that radius\_mean is highly correlated to some features like radius worst, perimeter\_worst, and area\_worst. You can retain radius\_mean and remove these three features.

This is a more magnified view of the features that are highly correlated to each other.

You will now evaluate the model on the features selected based on your observations. You can see that the metrics show the same values as when it was using 25 features. This indicates that the features were redundant because removing them didn't affect the model performance.

```
[22]: # Remove the features with high correlation to other features
subset_feature_corr_names = [x for x in names if x not in ['radius_worst', used_vorst']]

# Calculate and check evaluation metrics
subset_feature_eval_df = used_vorst_ evaluate_model_on_features(df[subset_feature_corr_names], Y)
subset_feature_eval_df.index = ['Subset_features']

# Append to results and display
results = results.append(subset_feature_eval_df)
results.head(n=10)
```

```
[22]:

     Subset features 0.973684 0.974206
                                         0.953488 0.97619 0.964706
                     Feature Count
     All features
                                30
     Strong features
                                25
     Subset features
                                22
     Subset features
                                22
```

Bonus challenge (not required): Look back again at the correlation matrix at the start of this section and see if you can remove other highly correlated features. You can remove at least one more and arrive at the same model performance.

#### 1.7.3 Univariate Selection with Sci-Kit Learn

Sci-kit learn offers more filter methods in its feature selection module. Moreover, it also has convenience methods for how you would like to filter the features. You can see the available options here in the official docs.

For this exercise, you will compute the ANOVA F-values to select the top 20 features using SelectKBest().

```
[23]: def univariate_selection():

# Split train and test sets
X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size = 0.

→2,stratify=Y, random_state = 123)

# All features of dataset are float values. You normalize all features of the train and test dataset here.

scaler = StandardScaler().fit(X_train)
X_train_scaled = scaler.transform(X_train)
```

You will now evaluate the model on the features selected by univariate selection.

# [24]: univariate\_feature\_names = univariate\_selection()

radius mean: True texture\_mean: True perimeter mean: True area mean: True smoothness mean: False compactness\_mean: True concavity\_mean: True concave points\_mean: True symmetry\_mean: False fractal\_dimension\_mean: False radius\_se: True texture\_se: False perimeter\_se: True area\_se: True smoothness\_se: False compactness\_se: False concavity\_se: False concave points se: True symmetry\_se: False fractal\_dimension\_se: False radius\_worst: True texture\_worst: True perimeter\_worst: True area\_worst: True smoothness\_worst: True compactness\_worst: True

```
concavity_worst: True
     concave points_worst: True
     symmetry_worst: True
     fractal_dimension_worst: False
[25]: # Calculate and check model metrics
      univariate_eval_df = evaluate_model_on_features(df[univariate_feature_names], Y)
      univariate_eval_df.index = ['F-test']
      # Append to results and display
      results = results.append(univariate_eval_df)
      results.head(n=10)

                                                                 0.953488
      Strong features
                                                        0.97619
                       0.973684
                                  0.974206
                                             0.953488
                                                                 0.964706
                                                        0.97619
      Subset features
                       0.973684
                                  0.974206
                                             0.953488
                                                                 0.964706
      Subset features
                       0.973684
                                  0.974206
                                             0.953488
                                                        0.97619
                                                                 0.964706
      F-test
                       0.973684
                                  0.974206
                                             0.953488
                                                        0.97619
                                                                 0.964706
                       Feature Count
      All features
                                   30
                                   25
      Strong features
                                   22
      Subset features
      Subset features
                                   22
```

You can see that the performance metrics are the same as in the previous section but it uses only 20 features.

20

## 1.8 Wrapper Methods

F-test

Wrapper methods use a model to measure the effectiveness of a particular subset of features. As mentioned in class, one approach is to remove or add features sequentially. You can either start with 1 feature and gradually add until no improvement is made (forward selection), or do the reverse (backward selection). That can be done with the SequentialFeatureSelector class which uses k-fold cross validation scores to decide which features to add or remove. Recursive Feature Elimination is similar to backwards elimination but uses feature importance scores to prune the number of features. You can also specify how many features to remove at each iteration of the recursion. Let's use this as the wrapper for our model below.

#### 1.8.1 Recursive Feature Elimination

You used the **RandomForestClassifier** as the model algorithm for which features should be selected. Now, you will use **Recursive Feature Elimination**, which wraps around the selected model to perform feature selection. This time, you can repeat the same task of selecting the top 20 features using RFE instead of SelectKBest.

```
[23]: def run_rfe():
          # Split train and test sets
          X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size = 0.
       →2,stratify=Y, random_state = 123)
          # All features of dataset are float values. You normalize all features of \Box
       → the train and test dataset here.
          scaler = StandardScaler().fit(X_train)
          X_train_scaled = scaler.transform(X_train)
          X_test_scaled = scaler.transform(X_test)
          # Define the model
          model = RandomForestClassifier(criterion='entropy', random_state=47)
          # Wrap RFE around the model
          rfe = RFE(model, 20)
          # Fit RFE
          rfe = rfe.fit(X_train_scaled, Y_train)
          feature_names = df.drop("diagnosis_int",1 ).columns[rfe.get_support()]
          return feature_names
      rfe_feature_names = run_rfe()
```

You will now evaluate the **RandomForestClassifier** on the features selected by RFE. You will see that there is a slight performance drop compared to the previous approaches.

```
[24]: # Calculate and check model metrics
    rfe_eval_df = evaluate_model_on_features(df[rfe_feature_names], Y)
    rfe_eval_df.index = ['RFE']

# Append to results and display
    results = results.append(rfe_eval_df)
    results.head(n=10)
```

```

## 1.9 Embedded Methods

Some models already have intrinsic properties that select the best features when it is constructed. With that, you can simply access these properties to get the scores for each feature. Let's look at some examples in the following sections.

### 1.9.1 Feature Importances

Feature importance is already built-in in scikit-learn's tree based models like RandomForest-Classifier. Once the model is fit, the feature importance is available as a property named feature\_importances\_.

You can use SelectFromModel to select features from the trained model based on a given threshold.

```
[25]: def feature_importances_from_tree_based_model_():
          # Split train and test set
          X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size = 0.
       →2,stratify=Y, random_state = 123)
          # Define the model to use
          scaler = StandardScaler().fit(X_train)
          X_train_scaled = scaler.transform(X_train)
          X_test_scaled = scaler.transform(X_test)
          model = RandomForestClassifier()
          model = model.fit(X train scaled, Y train)
          # Plot feature importance
          plt.figure(figsize=(10, 12))
          feat_importances = pd.Series(model.feature_importances_, index=X.columns)
          feat_importances.sort_values(ascending=False).plot(kind='barh')
          plt.show()
          return model
      def select_features_from_model(model):
          model = SelectFromModel(model, prefit=True, threshold=0.013)
          feature_idx = model.get_support()
          feature names = df.drop("diagnosis int",1 ).columns[feature idx]
          return feature_names
```

```
model = feature_importances_from_tree_based_model_()
feature_imp_feature_names = select_features_from_model(model)
```

```
[26]: # Calculate and check model metrics

## 1.9.2 L1 Regularization

L1 or Lasso Regulartization introduces a penalty term to the loss function which leads to the least important features being eliminated. Implementation in scikit-learn can be done with a LinearSVC model as the learning algorithm. You can then use SelectFromModel to select features based on the LinearSVC model's output of L1 regularization.

```
[27]: def run_l1_regularization():
          # Split train and test set
          X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size = 0.
       →2,stratify=Y, random_state = 123)
          # All features of dataset are float values. You normalize all features of \Box
       → the train and test dataset here.
          scaler = StandardScaler().fit(X train)
          X_train_scaled = scaler.transform(X_train)
          X_test_scaled = scaler.transform(X_test)
          # Select L1 regulated features from LinearSVC output
          selection = SelectFromModel(LinearSVC(C=1, penalty='l1', dual=False))
          selection.fit(X_train_scaled, Y_train)
          feature_names = df.drop("diagnosis_int",1 ).columns[(selection.
       →get_support())]
          return feature_names
      l1reg_feature_names = run_l1_regularization()
```

```
[28]: # Calculate and check model metrics
l1reg_eval_df = evaluate_model_on_features(df[l1reg_feature_names], Y)
l1reg_eval_df.index = ['L1 Reg']

# Append to results and display
results = results.append(l1reg_eval_df)
results.head(n=10)
```

| [28]: |                    | Accuracy | ROC      | Precision | Recall   | F1 Score | \ |
|-------|--------------------|----------|----------|-----------|----------|----------|---|
|       | All features       | 0.964912 | 0.967262 | 0.931818  | 0.976190 | 0.953488 |   |
|       | Strong features    | 0.973684 | 0.974206 | 0.953488  | 0.976190 | 0.964706 |   |

|       | Feature Importance | 0.956140 | 0.955357 | 0.930233  | 0.952381 | 0.941176 |   |
|       | L1 Reg             | 0.929825 | 0.929563 | 0.886364  | 0.928571 | 0.906977 |   |

|                    | ${\tt Feature}$ | ${\tt Count}$ |
|--------------------|-----------------|---------------|
| All features       |                 | 30            |
| Strong features    |                 | 25            |
| Subset features    |                 | 22            |
| F-test             |                 | 20            |
| RFE                |                 | 20            |
| Feature Importance |                 | 13            |
| L1 Reg             |                 | 18            |

With these results and also your domain knowledge, you can decide which set of features to use to train on the entire dataset. If you will be basing it on the f1 score, you may narrow it down to the Strong features, Subset features and F-test rows because they have the highest scores. If you want to save resources, the F-test will be the most optimal of these 3 because it uses the least number of features (unless you did the bonus challenge and removed more from Subset features). On the other hand, if you find that all the resulting scores for all approaches are acceptable, then you may just go for the method with the smallest set of features.

## 1.10 Wrap Up

That's it for this quick rundown of the different feature selection methods. As shown, you can do quick experiments with these because convenience modules are already available in libraries like sci-kit learn. It is a good idea to do this preprocessing step because not only will you save resources, you may even get better results than when you use all features. Try it out on your previous/upcoming projects and see what results you get!
